

## Fries Rearrangement of Anilides in the Presence of Phosphorus Pentoxide in Methanesulfonic Acid

Babak Kaboudin and Yaghoub Abedi

Department of Chemistry, Institute for Advanced Studies in Basic Sciences Gava Zang, Zanjan, Iran

Aminoaryl ketones are an important class of compounds that exhibit a variety of interesting and useful properties.<sup>1–3</sup> Some aminoaryl ketones are useful intermediates for the synthesis of benzodiazepines exhibiting activity as peptide antagonists, antivirals, antimalarials, and inhibitors of DNA interactions.<sup>4–7</sup> Moreover, *p*-aminoaryl ketones are useful intermediates in the synthesis of other compounds that are used as sunscreens, anti-inflammatory agents, dyes, and inhibitors of MAP kinases.<sup>8–11</sup> The Fries reaction of aryl esters is an important rearrangement in aromatic chemistry.<sup>12–14</sup> In contrast to the widely studied Fries rearrangement of phenolic esters, relatively few papers have been reported on the Fries rearrangement of anilides<sup>12</sup> to *o*- and *p*-aminoaryl ketones, by photolysis or thermolysis (above 200–350°C) with various Lewis acids such as ZnCl<sub>2</sub>, SnCl<sub>4</sub>, TiCl<sub>4</sub>, ThCl<sub>4</sub> and BiCl<sub>3</sub>.<sup>15–18</sup> The Fries rearrangement of acetanilide has been also reported over zeolite catalysts at 280°C with 50% conversion.<sup>19</sup> Recently a Fries-type rearrangement of anilides has been reported by using strong bases *via* an anionic rearrangement.<sup>20</sup>

Methanesulfonic acid is a Brønsted acid that is used as catalyst and solvent for condensation or rearrangement reactions.<sup>21–23</sup> Its use as catalyst in the Fries rearrangement of phenolic esters is already known.<sup>24–26</sup> Addition of P<sub>2</sub>O<sub>5</sub> increased the solubility of organic compounds in methanesulfonic acid that has been used extensively in organic synthesis.<sup>27</sup> As a part of our effort to explore methodologies for organic transformations,<sup>28–45</sup> we described a new method for the Fries rearrangement of phenolic esters for the synthesis of acylaryl methane sulfonates in the presence of POCl<sub>3</sub> in methanesulfonic acid.<sup>46</sup> Herein, we report the Fries rearrangement of anilides in the presence of a mixture of P<sub>2</sub>O<sub>5</sub> in methanesulfonic acid (1:7) as an efficient reagent for the selective synthesis of *p*-aminoaryl ketones.

The Fries rearrangement of benzanilide (**1a**), chosen as a model compound, was studied in the presence of P<sub>2</sub>O<sub>5</sub> in methanesulfonic acid, and the progress of the reaction monitored by TLC (*Scheme 1* and *Table 1*). Treatment of **1a** with a mixture of P<sub>2</sub>O<sub>5</sub> in methanesulfonic

Dedicated to Professor Hashem Sharghi on the occasion of his 60th birthday.

Received October 24, 2008; in final form March 27, 2009.

Scheme 1

acid (1:12) gave 4-aminobenzophenone (**2a**) in 8% yield after 48 h at 100°C (Table 1, Entry 2). Surprisingly, we found that increasing the amount of P<sub>2</sub>O<sub>5</sub> led to acceleration of the reaction rate and an increase in the yield of **2a** (Entries 3–6). We obtained the best results with 1:7 ratio of P<sub>2</sub>O<sub>5</sub> in methanesulfonic acid (Entry 6). The yield of the reaction did not change with increasing amounts of P<sub>2</sub>O<sub>5</sub>. Increasing the reaction temperature to 110°C also led to an increase in yield (Entry 9). Decomposition occurred when the reaction temperature was raised to 120°C. <sup>1</sup>H NMR studies on the Fries rearrangement of **1a** at different temperatures showed that at the beginning of the reaction, *p*-benzoylbenzanilide (**3a**) is the major product. Sulfonated products **5** and **8a** (Table 2) were detected in low yields (<10%) in the reaction mixture after 48 h. In a separate experiment, when compound

a) Yield refers to isolated yield by column chromatography.

b) Ratio of products was calculated after separation by column chromatography.

**3a** was added to a mixture of P<sub>2</sub>O<sub>5</sub>/methanesulfonic acid (1:7) and stirred for 48 h at 100°C, compound **2a** was formed in 90% yield.

These results may be explained by considering the initial formation of **3a** which undergoes decomposition to **2a**. The Fries rearrangement of benzanilide (**1a**) failed with a mixture of P<sub>2</sub>O<sub>5</sub>/methanesulfonic acid (1:7) in 1,2-dichloroethane, nitrobenzene, and chlorobenzene respectively at 100°C for 48 h.

The process was successfully extended to other anilides as summarized in *Table 2*. The Fries rearrangement of benzanilides (**1b–e**) with P<sub>2</sub>O<sub>5</sub>/methanesulfonic acid (1:7) afforded the desired products in 45–61% yields (*Table 2*). The reaction of *p*-nitrobenzoyl benzanilide (**1f**) in the presence of this reagent led only to sulfonated product (**8f**) as the major product. Treatment of acetanilide (**4a**) in the presence of P<sub>2</sub>O<sub>5</sub> in methanesulfonic acid failed for 48 h at 110°C failed. However at 115°C this reaction gave three products: **5**, **6a**, and **7a** in 1:1:1 ratio in 50% total yield. With this reagent, *N*-benzoyl-1-naphthylamine (**9a**) gave **10a**

in 32% yield after 48 h at 85°C, decomposition occurred after 48 h at 110 °C. In the case of *N*-phenylcinnamamide (**4b**), the cyclization product **11** was obtained as major product in 68% yield (Scheme 2). A sulfonated product **12** was also detected as a side-product in the reaction mixture (20% yield).

Scheme 2

In summary,  $\text{P}_2\text{O}_5$ /methanesulfonic acid (1:7) was shown as an efficient reagent in the Fries rearrangement of anilides to *p*-aminoaryl ketones. Studies on the reaction mixture showed that the reaction proceeded *via* the formation of *p*-acylated anilide (**3**). Some of the major advantages of this protocol are simple procedure, easy work-up, good yields, inexpensive and non-toxic catalyst, mild reaction conditions relative to other current methodologies, a lower reaction temperature than other methodologies and reactions with high selectivity for providing *p*-aminoaryl ketones. All reported methods to give a mixture of two products *p*- and *o*-aminoaryl ketones including other unknown mixture products. All NMR data could be assigned and are in good agreement with the product structures (Tables 3 and 4).

## Experimental Section

All chemicals were commercial products and distilled or recrystallized before use. All melting points were obtained on a Buchi 510 apparatus and are uncorrected. Infrared (IR) spectra were determined using a FT-IR Bruker-Vector 22. NMR spectra were obtained on a DMX-250 Bruker Avance spectrometer in  $\text{CDCl}_3$ . Silica gel column chromatography was carried out on Silica gel 100 (Merck No. 10184). Merck Silica-gel 60 F254 plates were used for preparative TLC.

### General Procedure for the Preparation of Anilides (1, 4, and 9)

Acid chloride or anhydride (10 mmol) was added to a stirred solution of anilide (10 mmol) in THF (50 mL). The mixture was stirred for 2 h at room temperature. A white solid precipitated which was filtered and washed with  $\text{H}_2\text{O}$  ( $5 \times 20$  mL). Pure anilide was obtained after recrystallization from AcOEt.

**General Procedure for the Fries Rearrangement of Anilides in the Presence of P<sub>2</sub>O<sub>5</sub> in Methanesulfonic Acid**

In a 50 mL round bottom flask, a mixture of P<sub>2</sub>O<sub>5</sub> (1 g) in methanesulfonic acid (5 mL) was stirred for 10 min at 80°C. The anilide (3 mmol) was added to the mixture and the reaction mixture was heated at 100–115°C for 48 h (The reaction progress was followed by TLC). The reaction mixture was quenched by adding water, neutralized with NaOH solution (50 mL, 10%) and extracted with chloroform (2 × 50 mL). The *p*-aminoaryl ketone was easily removed from the reaction mixture by extraction with HCl (50 mL, 10%). The aqueous phase was neutralized with NaOH (50 mL, 10%) and the product extracted with diethyl ether (4 × 25 mL). The solvent was evaporated and the product recrystallized from acetone. After separation of the *p*-aminoaryl ketone from the reaction mixture, the mother liquor (chloroform) containing unreacted anilide and other rearrangement products that were separated by column chromatography with *n*-hexane/ethyl acetate as eluting solvents (the ratio of solvent depends on the amides).

**4-Phenyl-3,4-dihydroquinolin-2(1H)-one (11)** white crystals, mp. 187–189°C (*n*-hexane/EtOAc); <sup>1</sup>H NMR (250 MHz, CDCl<sub>3</sub>): δ 2.95 (d, 2H, *J* = 7.0 Hz), 4.31 (t, 1H, *J* = 7.2 Hz), 6.90–7.05 (m, 3H), 7.15–7.48(m, 6H), 9.52 (s, 1H, NH); <sup>13</sup>C-NMR (62.9 MHz, CDCl<sub>3</sub>): 38.4, 41.9, 115.8, 123.4, 126.6, 127.2, 127.8, 128.0, 128.3, 128.9, 137.0, 141.5, 171.2.
