Received April 18, 2007

This study describes a novel one-pot procedure for a directly reductive conversion of the carbonyl function of esters to the corresponding ethers by Et₃SiH in the presence of a catalytic amount of InBr₃.

Previous methods for the preparation of ethers involved the reaction of an alkoxy anion with an alkyl halide/sulfonate under basic conditions (Williamson synthesis) and the acid-promoted dehydrogenate condensation of alcohols.¹ Since the 1960s, the representative preparation of ethers has been a direct reduction of a carbonyl function of esters and thioesters.¹ Although a number of protocols for the direct reduction of esters and thioesters have been developed, most were accomplished through treatment with stronger reducing agents, such as LiAlH₄² and DIBAL,³ or a more toxic reagent, such as organotin hydride,⁴ or by use of a complicated transition-metal complex.⁵ In addition, these require γ -ray⁶ or UV irradiation.⁷ Thus, from

the viewpoint of handling, workup, and environmental impact, development of a highly simple reductive procedure of esters, which proceeds under milder conditions, is needed. On the other hand, several groups have recently reported that a combination of a trivalent indium salt and a milder reducing reagent, a hydrosilane, is an effective reagent system for the reductive conversion of a functional group involving dehalogenation of organic halides, reduction of an alcohol, 1,4-reduction of enones, and reductive aldol reaction.8 In this context, the reductive C-O bond cleavage of propargylic acetates using InBr₃-Et₃SiH to produce an internal alkyne was demonstrated.9 During ongoing investigations on the development of the selective deacetoxylation of several organic compounds using the InBr₃-Et₃SiH system, remarkably it was found that, unlike our previous result,9 the InBr₃-Et₃SiH reducing system causes the reduction of the carbonyl function of esters under milder conditions, resulting in the preparation of unsymmetrical ethers.^{10,11} Thus, we report herein on a further study of the present reductive procedure.

Initially, the reduction of phenethyl acetate (1a) with Et₃SiH in the presence of 0.05 equiv of InBr₃ as a model reaction was studied.¹² Table 1 shows the results of the search for optimized conditions. It was found that chloroform was the best solvent for this reaction (run 1). Benzene and toluene also showed a similar effect (runs 2 and 3). However, when the reaction was conducted in THF, the reaction did not proceed (run 4), and the use of acetonitrile also resulted in decreased yields (run 5). On the other hand, it was noted that when the similar reaction was carried out using InCl₃, In(OAc)₃, and In(OTf)₃, the desired ether product was not obtained, resulting in the recovery of the starting acetate (runs 6-8). Then, running this reaction with (EtO)₃SiH, instead of Et₃SiH, produced a low yield (run 9). In contrast, a reducing reagent, such as PhMe₂SiH, was effective for this reaction (run 10). Consequently, it was found that the combination of 0.05 equiv of InBr₃ and 4 equiv of Et₃SiH in chloroform gave the best results for the reaction.¹³

To generalize this reaction, the reduction of various esters **1** was carried out under optimized conditions with the reactions typically run at 60 °C in a CHCl₃ solution. The results are displayed in Table 2. In most cases, the reduction of esters with no relation to the length of the alkyl chain was completed in a

TABLE 1 Examinations of Reaction Conditions

short time, producing the corresponding ethers 2 in good yields. Although more time was required for the reaction of the ester **1c** having a nitro group on the benzene ring to complete the reaction, it was found that the nitro group is tolerant toward the InBr₃-Et₃SiH system. A type of substituent next to the carbonyl group, other than the methyl group, could be extended to a linear carbon chain and to a branched carbon chain (entries 5 and 6). When the reaction with the ester 1g, which reverses the location of the ester group, was carried out, the corresponding ether 2a was also produced in excellent yield (entry 7). Moreover, a bromide substituent on a benzene ring was not affected by the reducing system (entry 8). By contrast, the reduction using the ester 1i derived from benzoic acid was rather sluggish in the completion of the reaction (entry 9). On the other hand, the reduction using both the linear acetate 1j derived from the primary alcohol and the branched acetate 11 derived from the secondary alcohol gave the alkyl ethers 2j,l in good yield, respectively (entries 10 and 12). Also, ester 1k having a bromide substituent was chemoselectively converted to the corresponding ether 2k in 73% yield, and it appeared that a halogen atom on a primary carbon is tolerant of the reducing reagent (entry 11). The reduction of a heteroaromatic ester containing a thiophene ring also reached 55% yield (entry 13). This method appeared to be a useful tool for the preparation of cyclic ethers 2n,o under mild conditions (entries 14 and 15). This protocol appears to be a highly simple and practical method for preparation of a series of ether frameworks, the structure of which broadens in the central skeleton of fragrant compounds, such as perfumery and flavor.14

By contrast, when the reaction of the acetates **3a,b** derived from diphenylmethanol and α -methyl benzyl alcohol was carried out in the presence of 0.05 equiv of InBr₃ and 2 equiv of Et₃-SiH at room temperature, the desired ether product did not form, but the deacetoxylation of the starting materials clearly occurred to produce diphenylmethane (**4a**) and ethylbenzene (**4b**) (Scheme 1). Similarly, the reaction using the ester having a conjugated olefin moiety produced β -ethylstyrene (**4c**) along with geometric isomer **4c'**. Thus, it was found that in the case of the acetoxy group on the secondary carbon bonding to a phenyl group or a conjugated double bond the deacetoxylation predominately proceeds.

^a Average of two runs. ^bThe silyl ether was also obtained in 36% yield.

pounds under optimal conditions, and the results are summarized in Scheme 2. For example, the reductive deoxygenation using thioacetate¹⁵ **5a** and amide **5b** was examined. Unfortunately, the desired sulfide **6a** does not form nor does secondary amine **6b**. Although the InBr₃–Et₃SiH system underwent the reduction of a carboxylic acid to produce the corresponding primary alcohol **6c** in 32% yield along with the silyl ether product,¹⁶ treatment of ketone **5d** with the reducing system gave the corresponding symmetrical ether derivative **6d** in good yields.¹⁷

When 2,2,6,6-tetramethyl-1-piperidinyloxy radical (TEMPO), a radical scavenger, was added to the reaction mixture containing ester **1a**, InBr₃, and Et₃SiH, the desired reduction was suppressed, and the starting ester was recovered. Thus, in situ generation of the indium radical species would play a key role in the promotion of this reductive process. A plausible mechanism for the reaction is shown in Scheme $3.^{8f,18}$ The reaction path involves the following steps: (i) transmetalation between Et₃SiH and InBr₃ as an initial step, (ii) a consecutive abstraction of hydrogen by the radical intermediate and the formation of an ether product, and (iii) finally, the regeneration of an indium radical species. Accordingly, in case of the ester **1i** (R¹ = Ph), a resonance effect of the generated secondary (benzyl) radical with a benzene ring would hinder the hydrogen abstraction step, resulting in the sluggish reduction of the ester.

In conclusion, we demonstrated that the InBr₃ and Et₃SiH reagent system promotes direct and selective reduction of esters to produce corresponding unsymmetrical ethers. This simple catalytic system appeared to be remarkably tolerant to several functional groups and was applicable to the other functional groups, such as a carboxylic group. Further studies on the reduction of other types of functional groups are in progress.

Experimental Section

General Procedure for the Reduction of Esters Using the InBr₃-Et₃SiH System. To a freshly distilled CHCl₃ solution (0.6 mL) in a screw-capped vial under N2 atmosphere were added successively ester 1 (0.6 mmol), InBr₃ (10.6 mg, 0.0300 mmol), and Et₃SiH (380 μ L, 2.40 mmol), and the vial was sealed with a cap containing a PTFE septum. During the stirring of the reaction mixture at 60 °C (bath temperature), the solution turned from colorless to yellow, then to orange. The reaction was monitored by GC analysis until consumption of the starting ester. After the reaction, H₂O (3 mL) was added, and the resulting orange suspension was stirred continuously until the disappearance of the color. The aqueous layer was extracted with CH₂Cl₂ (15 mL), the combined organic phase was dried over anhydrous Na₂SO₄, filtered, and then evaporated under reduced pressure. The crude product was purified by flash column chromatography (SiO₂/hexane:AcOEt = 99:1) to give the corresponding ether 2.

Ethyl Phenethyl Ether (2a): colorless oil; ¹H NMR (500 MHz, CDCl₃) δ 1.20 (t, 3H, J = 7.5 Hz), 2.90 (t, 2H, J = 7.5 Hz), 3.50 (q, 2H, J = 7.5 Hz), 3.63 (t, 2H, J = 7.5 Hz), 7.22 (m, 3H), 7.28 (m, 2H); ¹³C NMR (125 MHz, CDCl₃) δ 15.2, 36.4, 66.2, 71.6, 126.1, 128.3, 128.9, 139.0; MS (EI) m/z 150 (M⁺), 105 (100%).
